Experiment-4

Aim: To create accounts in MetaMask and transfer cryptocurrency from one account to another using the Ethereum blockchain.

Software Requirements

- MetaMask browser extension
- Google Chrome
- Internet connection
- Ethereum test network, such as Sepolia, or a local development blockchain
- Test ETH for performing transactions

Important: We'll use test cryptocurrency, not real money. Do not share your Secret Recovery Phrase or private keys with anyone.

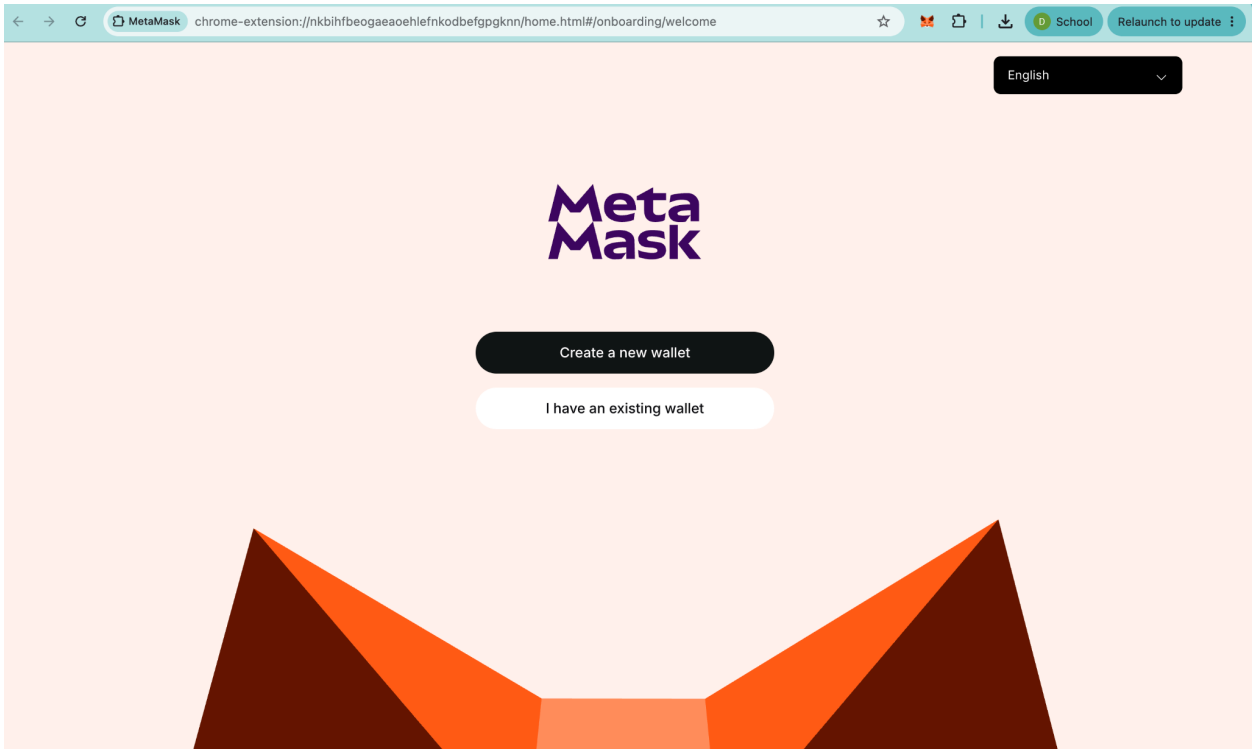

Theory

MetaMask is a cryptocurrency wallet that allows users to create and manage blockchain accounts, store digital assets, and send or receive cryptocurrency.

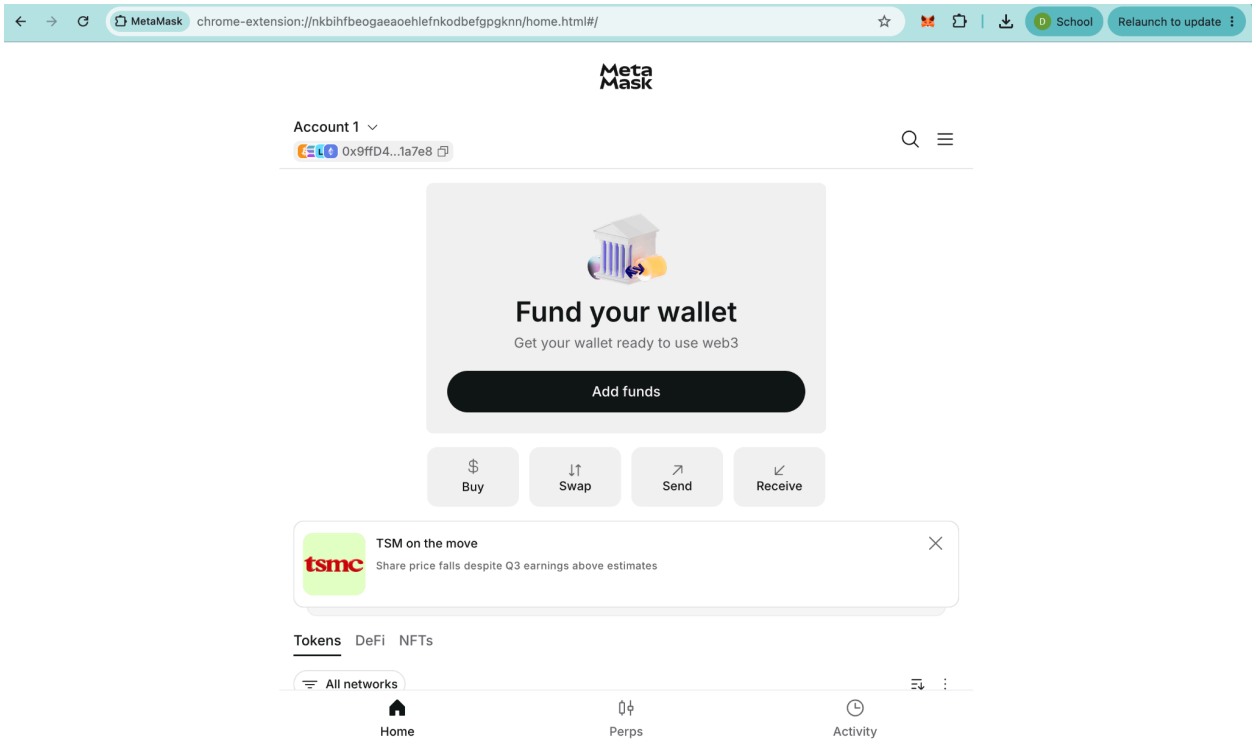

Each account has a public wallet address that can be shared to receive funds. A private key controls the account and must be kept secret.

A cryptocurrency transfer involves the sender's address, receiver's address, transfer amount, and a transaction fee called gas. Once a transaction is submitted and confirmed on the blockchain, it receives a transaction hash that can be used to verify its status.

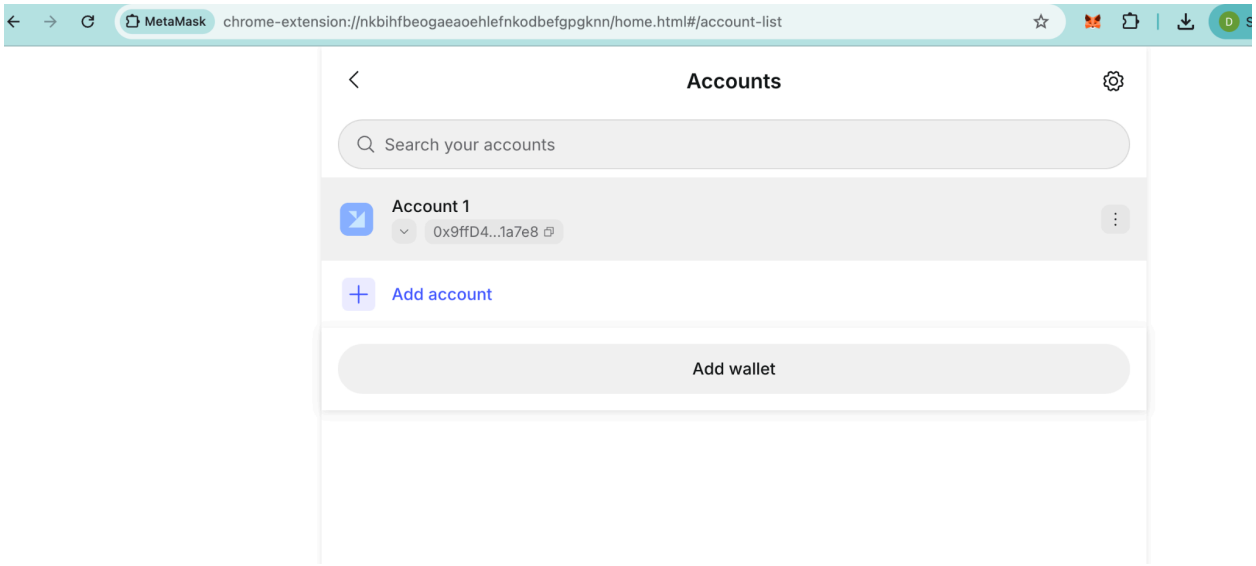

Step 1: Install MetaMask

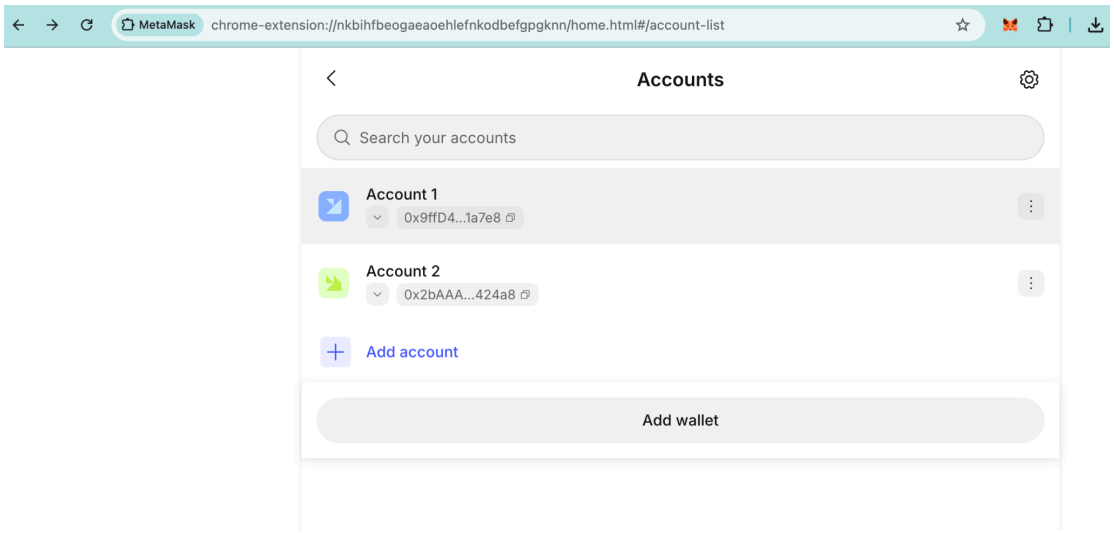

Step 2: Create a new wallet

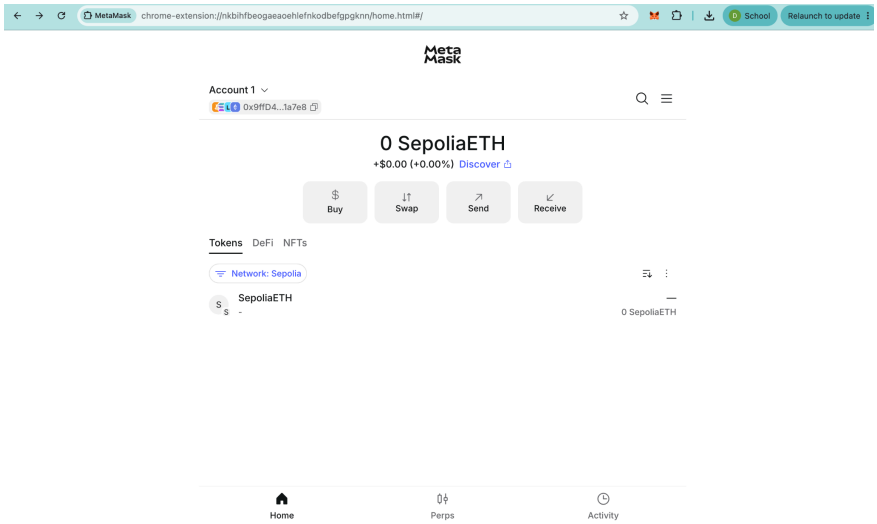

Step 3: Create a second account

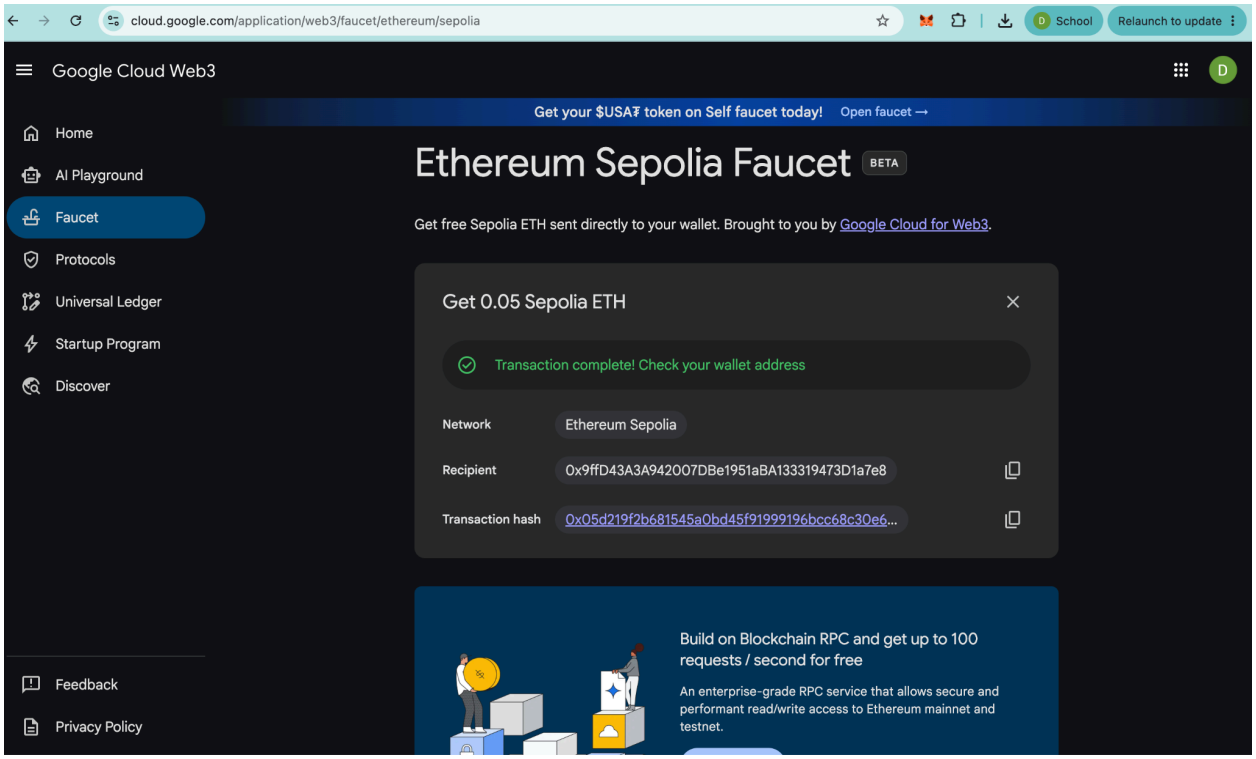

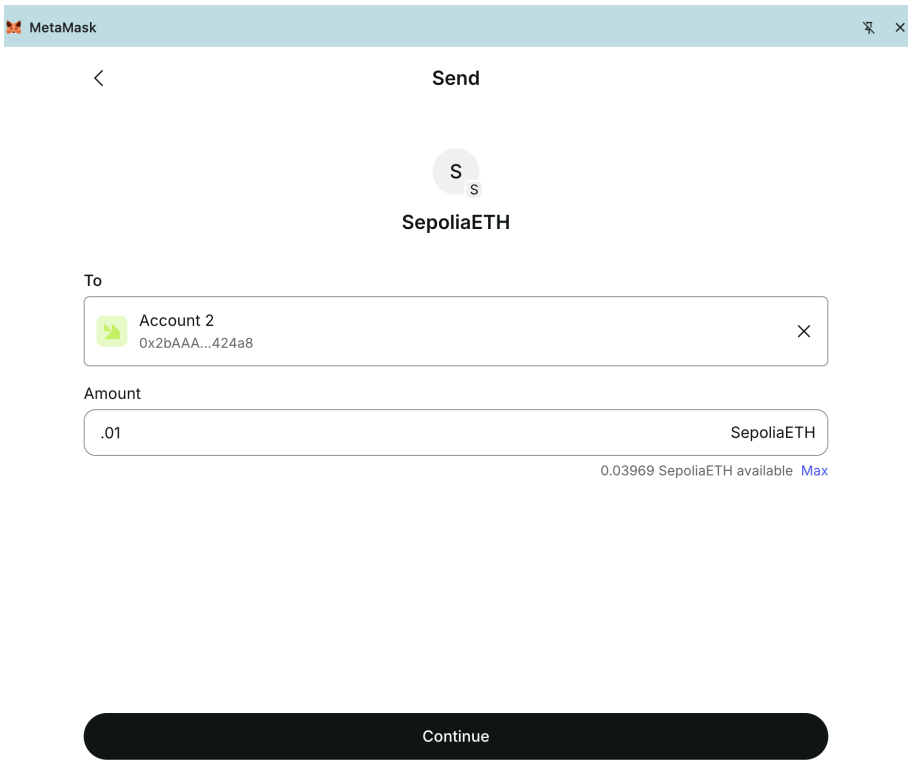

Step 4: Enable the Sepolia test network

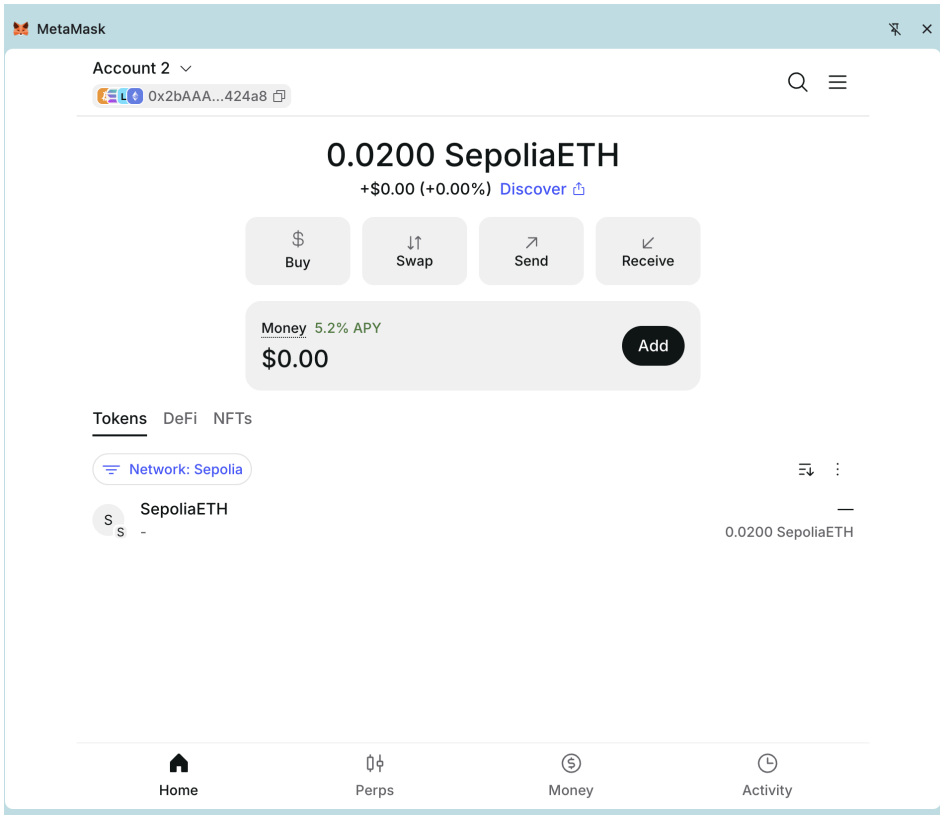

Step 5: Obtain test ETH

Step 6: Transfer ETH from Account 1 to Account 2

Step 7: Verify the transaction

Conclusion:Thus, MetaMask accounts were created successfully, and cryptocurrency was transferred from Account 1 to Account 2 using the Sepolia test network. The transaction was verified successfully.
